Model Optimization and Tuning Phase

The Model Optimization and Tuning Phase involves refining neural network models for peak performance. It includes optimized model code, fine-tuning hyperparameters, comparing performance metrics, and justifying the final model selection for enhanced predictive accuracy and efficiency.

Hyperparameter Tuning Documentation (8 Marks):

Model	Tuned Hyperparameters
Xception model	To optimize the performance of the Xception model, hyperparameters such as the number of epochs must be tuned carefully. The number of epochs specifies how many times the entire dataset will pass through the network during training. A higher number of epochs may lead to overfitting if the model starts to memorize the training data rather than generalizing well to unseen data. Hence, it's important to tune it to find an optimal value that results in good generalization. It ensures the model converges efficiently and avoids overfitting or underfitting.

Final Model Selection Justification (2 Marks):

Final Model	Reasoning
	The Xception model is often chosen for Alzheimer's disease prediction
	due to its superior feature extraction capabilities, particularly in
Xception model	handling complex patterns in medical imaging. Its architecture, based on depthwise separable convolutions, enables efficient learning of

spatial and channel-wise features, which is crucial for identifying subtle changes in brain scans. Xception is computationally efficient, reducing the risk of overfitting while delivering high accuracy. It has shown strong results in Alzheimer's studies, outperforming other models like ResNet and VGG in tasks requiring detailed pattern recognition. Its compatibility with transfer learning and scalability further solidify its role as an ideal choice for predicting Alzheimer's disease.
